

Model-Observation Integration: Approaches, Challenges, and Opportunities

## Deep Convection & Radar

“Simulating isolated storms observed during TRACER using NU-WRF EPIC, a high-resolution weather model with polarimetric radar forward-simulation and prognostic electrification”

Toshi & Marcus

# Forecasting microphysics, convection, lightning and polarimetric radar during TRACER IOP

POLARRIS

KHGX

Cell Duration (minutes)

Max Cell Area, km<sup>2</sup>

Inline POLARRIS suppress overestimated cell features and numbers from WRF radar composite (direct output).

# Finding Golden Cases

Isolated Deep Convection

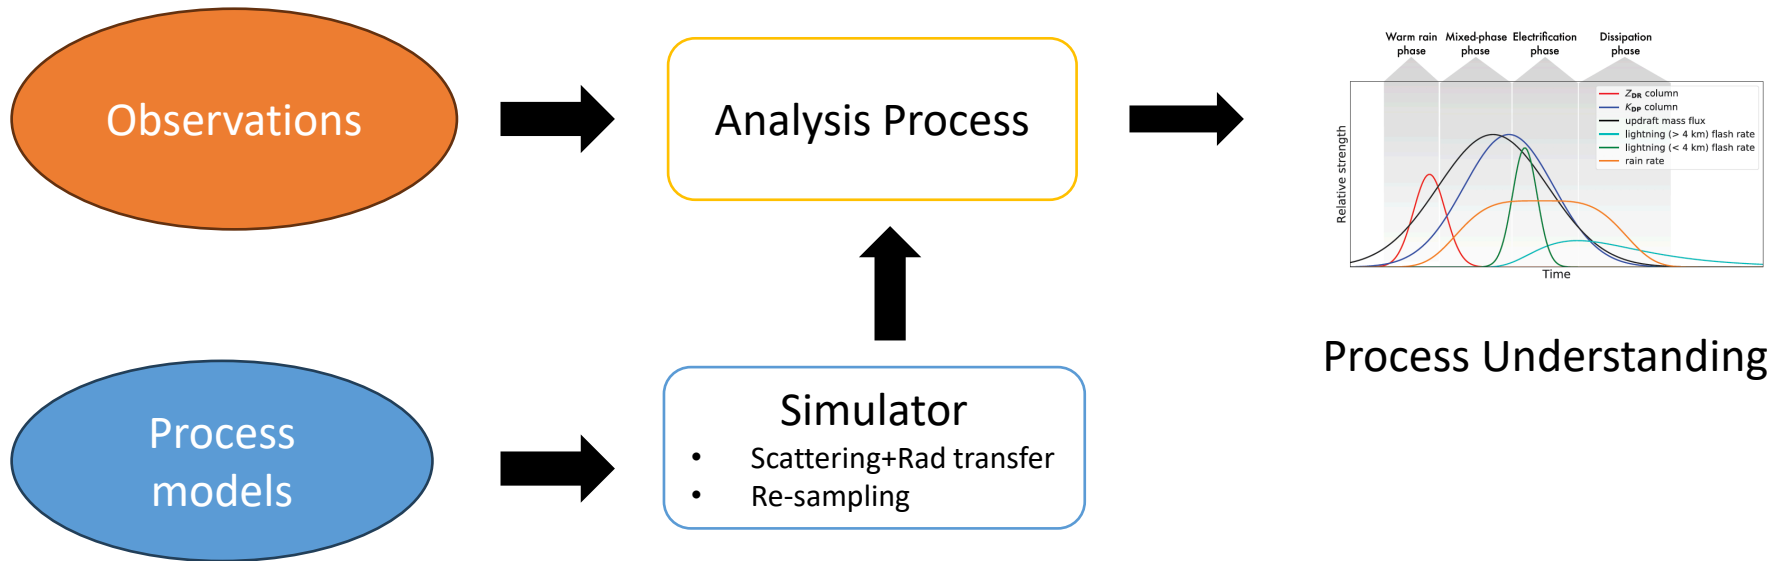

NUWRF-EPIC Skill Score Time Series 0h-24h

NUWRF-EPIC skill scores and isolated deep convective cells (IDC) counts are correlated each other. (Higher skills → More isolated deep convections)

# Observation-Model Integration

## Keys of observation-model integration

1. Same statistics analysis should be conducted between observations and process models.
2. Simulators play roles to convert model-derived parameters close to observations.
3. Tight collaboration between observation and modeling scientists is CRITICAL.

# How best to sample with radars?

- **Desirables:**

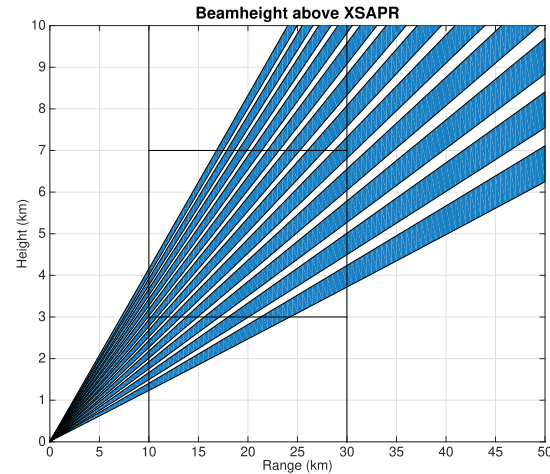

- Fast scanning to capture microphysics of (sub 1-minute) thermal evolution
- Volumetric information --- 2D scans can miss important aspects of 3D thermals

- **Realistic constraints:**

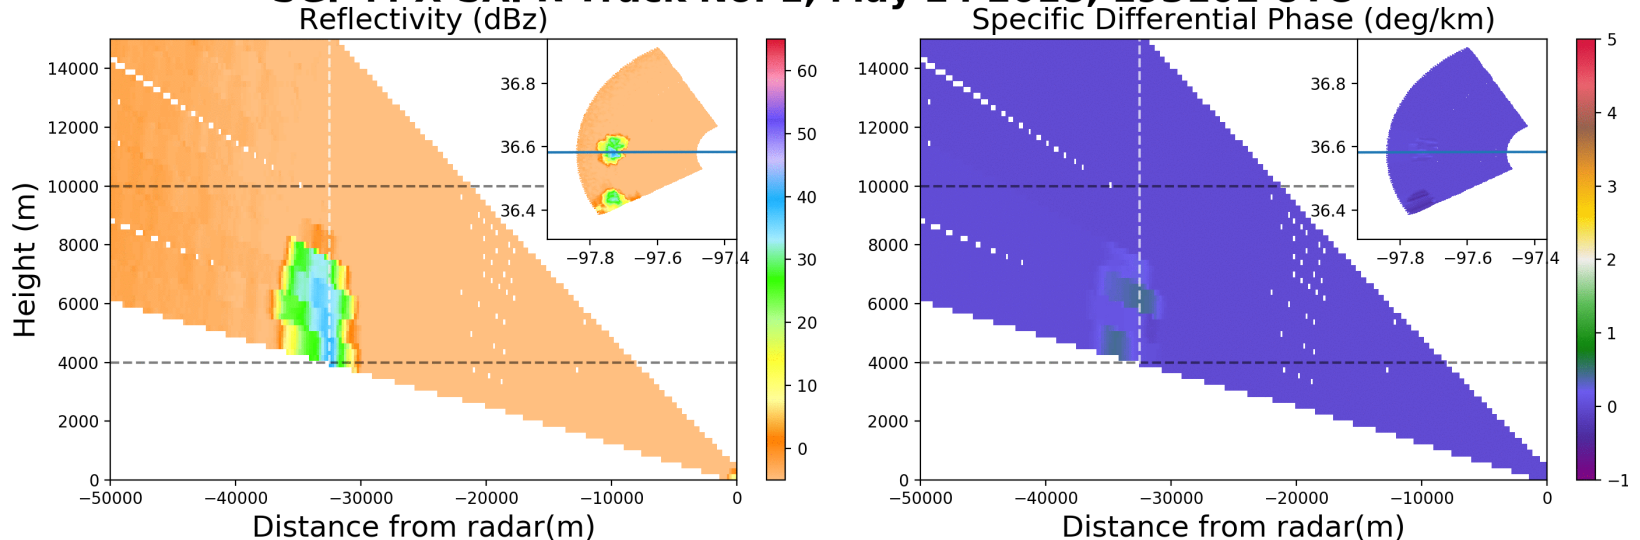

- Probably don't have, e.g. Phased Array Radars, so scanning rate is limited, so we must limit scan domain and actively target cells.
- Spinning dish radars don't like doing limited-sector PPIs, so might need to stick to RHIs
- What is a "target"? How do we prevent preferentially sampling "interesting" but unrepresentative population of convective storms?

# One past approach: 2018 X-SAPR experiment

- X-SAPRs were run in limited angle (roughly 90 degree) PPIs, targeting a “sweet spot” for mixed-phase processes every 120 sec

**SGP i4 X-SAPR Track No. 1, May 24 2018, 193102 UTC**

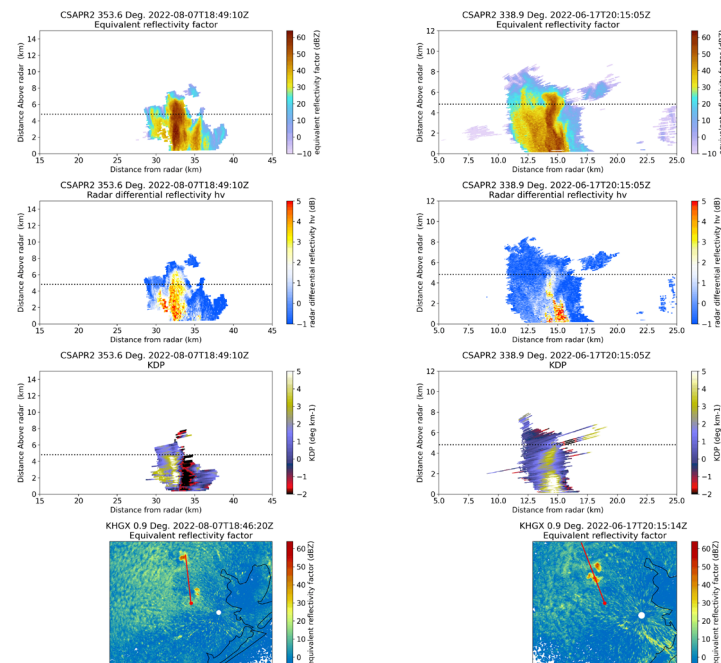

# TRACER C-SAPR2 scan strategy

- Use satellite and radar information to identify target cells
- Perform 3 PPIs, 1-6 RHIs (see chart from Mariko Oue ->)
- Are cells sampled for full lifecycle?
- Do the RHIs represent most *meaningful* slices through 3D thermal volume?
  - What does this even mean??

Time period	PPI	RHI
06/01/22 – 06/15/22	PPI <sub>1</sub> : cell top PPI <sub>2</sub> : cell middle PPI <sub>3</sub> : 3° elevation	RHI <sub>1</sub> : cell centroid
06/16/22 – 08/01/22		RHI <sub>1</sub> : cell centroid    RHI <sub>3</sub> : cell max Z RHI <sub>2</sub> : cell max VIL    RHI <sub>4</sub> : cell max Z <sub>DR</sub>
08/02/22 – 09/08/22		RHI <sub>1</sub> : cell centroid    RHI <sub>4</sub> : cell max Z <sub>DR</sub> RHI <sub>2</sub> : cell max VIL    RHI <sub>5</sub> : cell max Z RHI <sub>3</sub> : cell max Z        RHI <sub>6</sub> : cell max Z <sub>DR</sub>
09/09/22 – 09/30/22		RHI <sub>1</sub> : cell centroid    RHI <sub>4</sub> : cell max $\frac{\Delta''}{\Delta S}$ RHI <sub>2</sub> : cell max VIL    RHI <sub>5</sub> : cell max Z RHI <sub>3</sub> : cell max Z        RHI <sub>6</sub> : cell max $\frac{\Delta''}{\Delta S}$

## Some conclusions (or lack thereof...)

- It's clear we want high spatial and temporal resolution 4D observations to compare to model thermals
  - This ideal should motivate whatever approach is taken
- It is *not* clear how best to approximate this ideal given the limitations of currently available
  - There is a temporal lag between when measurements are taken and when scientists start complaining about them
